

# Ray-tracing reflection spectra of black-hole binaries

Frédéric Vincent<sup>1</sup>  
& Agata Róžańska<sup>1</sup>

<sup>1</sup>Centrum Astronomiczne M. Kopernika, Warsaw, Poland

# Contents

- 1 GR reflected spectra
- 2 Spectrum angle and spin dependence

## Reflection spectrum

- X-ray source (lamp)
- Reprocessed in the disk
- Emitted spectrum = thermal + Compton + lines

## Agata's code

- Hydro equilibrium: slim disk (Sądowski+11)
- Radiative transfer: PL, BB, Compton, iron lines
- Radiative equilibrium

## End product

- $I_\nu(r, \theta) \rightarrow$  raytracing  $\rightarrow$  observable spectrum

## Agata's code: parameters

- BH:  $M = 10 M_{\odot}$ ,  $\dot{m} = 0.01 \dot{m}_{\text{Edd}}$ ,  $a = 0$  or  $0.98$
- Lamp:  $\alpha = 0.7$  ( $I_{\nu}^{\text{lamp}} \propto \nu^{-\alpha}$ ),  $z_{\text{lamp}} = 5 r_S$
- Ionization parameter:  $\log \xi \approx 6$

## Comparing spectra

- Raytraced spectrum; Agata's "local" spectrum
- GR broadening of the line

# GR effects

## Redshift effect

- $\nu^{\text{obs}} = g \nu^{\text{em}}$  ( $g$  redshift factor)
- $I_{\nu}^{\text{obs}} = g^3 I_{\nu}^{\text{em}}$  [... movie ...]

## Beaming

- High inclination  $\rightarrow$  flux peaked at a small location

## Lensing effect

- Emitted angle different from inclination angle

## My question

- Is it important to compute **directional** intensities?
- Does BH **spin** impact the spectrum?

## Why is it important?

- People use angle-averaged spectra to constrain spin
- See Garcia et al. 2014
- Same study with independent codes

# Contents

- 1 GR reflected spectra
- 2 Spectrum angle and spin dependence

## Spectra for spin 0

- Question: understand spectra in the region [1 – 10] keV
- Why is the directional spectrum below at low  $i$  and above at high  $i$ ?

## Spectra for spin 0

- Important effect, up to 50% difference!

0.1 keV

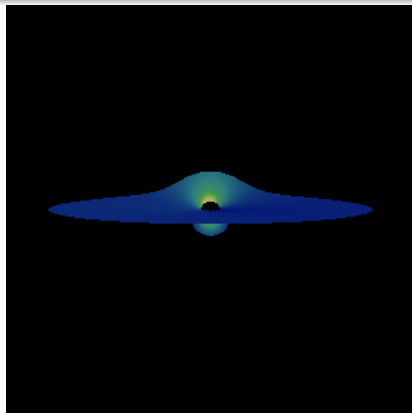

10 keV

Where does flux comes from?

- Answer:  
from the **center** for [1 – 10] keV

$i = 5^\circ$

$i = 85^\circ$

### How varies the emission angle?

- Answer:  
 $5^\circ$ : rather constant;  $85^\circ$ : more spread
- *But*: beaming  $\rightarrow$  angle always rather **constant**:  $\theta^{\text{em}} \approx i$

## Intensity variation

- $I_\nu(\mu)$  at  $r \approx 5 r_S$  and  $\nu = 10$  keV
- $5^\circ$ : directional is 50% below averaged
- $85^\circ$ : directional is 50% above averaged

## Spectra for spin 0: explanation

## Spectra for both spins

- Factor of  $\approx 10$  more flux at high spin
- Because disk goes closer to BH and is hotter at every  $r$
- $T(r = 3 r_S, a = 0) \approx 6 \times 10^5$  K;  
 $T(r = 3 r_S, a = 0.98) \approx 4 \times 10^6$  K
- Higher spin/inclination : broader redshift range;  
 continuum varies more near iron line at spin 0.98;  
 $\rightarrow$  iron line less visible at higher spin

## Spectra for both spins

- $I_\nu(\mu)$  at  $r \approx 5 r_S$  and  $\nu = 1$  keV
- Factor of  $\approx 10$  in intensity  $\rightarrow$  factor of  $\approx 10$  in spectrum

## Conclusion

- BH parameters constrained from angle-averaged spectra
- $\approx 50\%$  difference due to averaging whatever the spin
- Take spin into account properly for continuum + line

## Conclusion

- BH parameters constrained from angle-averaged spectra
  - $\approx 50\%$  difference due to averaging whatever the spin
  - Take spin into account properly for continuum + line
- Thanks for your attention!
